Design & Operation of Rooftop Photovoltaic System with Net-Metering Mechanism

Mr. David Voraganti¹, Dr. M. Narendra Kumar²

¹Assistant Professor, Dept. of EEE, Guru Nanak Institute Technology, Hyderabad, India
²Professor, Dept. of EEE, Guru Nanak Institute Technology, Hyderabad, India

ABSTRACT: A rooftop photovoltaic system generates electricity by using solar panels mounted on the rooftop of a residential or building. It is typically in the range of 5 to 20 kilowatts (kW) for residential buildings. The metropolitan cities facilitate the empty rooftop spaces and can naturally avoid the feasible land use and environmental concerns. Feed-in tariff (FIT) or Net-Metering mechanism is to sell the generated electricity to the grid at a price higher than what the grid charges for the consumers. This FIT mechanism provides payback for the investment of the consumer and also localize production and reduce transmission losses through power lines. Consumer can feed solar power into the electric grid and hence receive a premium tariff per generated kWh reflecting the benefits of solar power to compensate for the extra costs of usual electricity.

KEYWORDS: Net-Metering; PV System; Solar Energy; Semiconductors; Rooftop.

I. INTRODUCTION

Globe population is projected to twice by the middle of the 21st century (Global Energy, 1998). Population growth will consequently increase 3-5 times by the year 2050, and a 10-15 times by 2100. As a result, power necessities are amplified by three folds by the year 2050 and five folds by the year 2100. The use of renewable energy is possible alternative of burning fossil fuels.

- Minimum or no ecological consequences
- Some ecological consequences
- High ecological consequences
Solar energy is one of the practicable options. This form of Non-Conventional energy occupies less space compared to the space occupied Conventional energy. Table 1.1 tabulates various Conventional and Non-Conventional energy sources in terms of consequences and harm to the atmosphere. The first solar cell was created in 1883. The revolution in solar cell technology came in 1954 by Bell Laboratories stumbled across the photovoltaic (or PV) properties of silicon. Present commercial PV cells have enhanced to 11–15% efficiency.

The choice of Net-Metering, or interconnecting a customer producing electricity to the utility grid, makes solar electric systems more reasonably practicable. The metropolitan atmosphere provides a bare rooftop spaces and will provide space for production of solar electricity with the rooftop PV cells. Feed-in tariff (FIT) or Net-Metering mechanism is to trade the generated electricity to the grid and payback to the installer. It also improved capability for localized production and implanted generation reduces transmission losses in power lines.

II. PRINCIPLE OF OPERATION OF SOLAR POWER

The Sun is ultimate source for the world; the quantity of solar energy incident on the earth’s is approximately 1.5 x 1018 kWh/year, which is about 10,000 times of annual energy consumption by world. The density of power radiated from the sun is 1.373 kW/m². Solar cell is a piece of equipment which converts photons in light to direct-current (DC) and voltage. The associated technology is called Solar Photovoltaic (SPV). A silicon PV cell is a thin wafer consisting of a very thin layer of phosphorous-doped (N-type) and a thicker layer of boron-doped (P-type) silicon.

![Figure 2.1: Silicon Solar Cell](image)

When the sunlight falls on the semiconductor material; an electron energized and moves towards the N-type material. This will cause negatives charged particles in the n-type and positives charged particles in the P-type semiconductors, generating flow of electricity. This is known as Photovoltaic effect. Figure 2.1 shows the working method of a silicon solar cell.

III. THE COMPONENTS OF A GRID-TIED PV SYSTEM

This includes:

**PV Array:** PV array is installation of various PV panels together. Installing these arrays on rooftops is most common (say 200W×6 Panels)

**DC Disconnect:** The DC Disconnect acts like a protective switch, when this switch is opened manually; the circuit becomes open and stops power supply from the PV array to the Consumer system.

**DC/AC Inverter:** The Photo Voltaic module generates Direct Current (D,C) power; however, we use Alternating Current (AC) power for house hold needs and Power Grids. The Inverter is used to converts the DC power to AC power by switching devices.
AC Disconnect: It is another protective switch and is habitually built-in into the Inverter.

Production Meter: Output Energy (KWh) is measure by Production Meter by PV array and records the amount of electricity produced.

Building Breaker Box and Standard Utility Meter: Other name for Utility Meter is building’s circuit panel or electrical service panel. If the building is using electricity, the PV-produced electricity will be used first. If the building needs more electricity than the PV System is producing, utility grid power is automatically pulled into the building. When the PV System produces more electricity than is needed, the excess flows back out to the utility, spinning your utility billing meter backwards in the process. You earn credit for the excess power produced and can use that credit when the System is not producing energy. This process is referred to as “net metering.”

IV. DESIGNING ROOFTOP PV SYSTEM (CASE STUDY)

A. Case description

A small home in a city of Hyderabad wants to supply Electricity from APSEB mains and also use solar energy to all loads. The house is to be occupied in different time intervals, first from 6am-10am, 10am-5 pm, 5pm-10pm and 10pm-6am during the month. The home has four rooms and different electrical appliances.

B. Typical Rooftop System Design

1. Design Assumptions
   • Latitude (Hyderabad City) 17.37°N
   • Longitude (Hyderabad City) 78.48°E
   • Battery LMS400
   • Depth of discharge 0.8
   • Array output efficiency 85%
   • Inverter η% 90%
   • Battery η% 85%

2. PV Module Design
   • Model ELDORA 250P
   • Rated Peak Power (Pmpp) 255W
   • O.C Voltage (Voc) 89.7V
   • S.C Current (Isc) 3.51
   • Vrated (Vmpp) 82.77V
   • Irated (Impp) 3.1A
   • Fill Factor (FF) 76.78%
3. Inverter Capacity

- **Type**: MSW (Modified sine Wave)
- **Phase**: Single Phase
- **Power Rating**: 1.5 kVA
- **Voltage Rating**: 80V/230V
- **Frequency**: 50Hz

C. Assessment of Load profile

Assessment of load profile includes the variety of appliances, wattage and the number of hours operated a day. The associated appliances in the house are tabulated in table 4.1.

<table>
<thead>
<tr>
<th>No.</th>
<th>Appliance</th>
<th>Qty</th>
<th>Rated wattage</th>
<th>Operational hours / day</th>
<th>Energy / day (Watt-hours)</th>

</tbody>
</table>

| Total Power Consumption /day | 12,188Wh =12.2KWh =12.2Units/day |

*Assumed that the Air Conditioner/Refrigerator functions for 24 hours in a day, whereas compressor for 5 hours per day.

D. Assessment of Solar Generation profile

Assessment of source profile includes the Rooftop PV Modules with 6 No of panels. Each panel rating is of 200W. The number of hours the PV cell will operate a day is 6hr as tabulated below in table 4.2.

</tr>
</tbody>
</table>
V CONCLUSION

From the load assessment profile with 1KW load, the energy consumed is 12.2 Units/day. Therefore per month it becomes 366 Units/Month. As per normal tariff rates without Net-Metering per month become

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

By using the Net metering, from the solar power generation, the No.of units generated is around 175.78 Units/Months.Net Energy consumed by the consumer is (366-175.78=190 Units) So the tariff paid is shown in Table 4.5

<table>

<td>175.78</td>
<td>818</td>
</tr>
<tr>
<td>Net Saving</td>
<td>190 Units</td>
<td>1150</td>
</tr>
</tbody>
</table>

It can be concluding that by using the Net-Metering, the annual saving will be around 40%.
